# Advanced DevOps Lab Experiment:3

**Aim**: To understand the Kubernetes Cluster Architecture, install and Spin Up a Kubernetes Cluster on Linux Machines/Cloud Platforms.

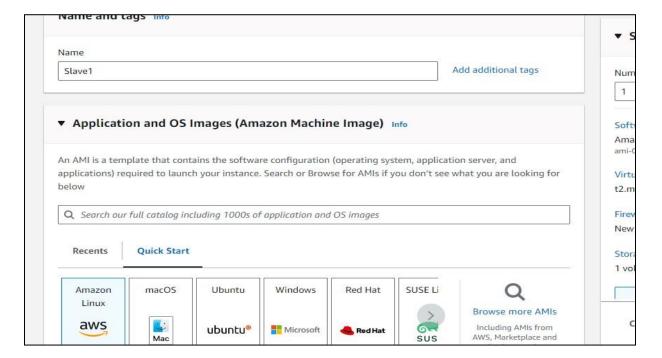

# Theory:

To understand Kubernetes Cluster Architecture and how to install and spin up a Kubernetes cluster on Linux machines or cloud platforms, it's essential to grasp the fundamental components and design principles of Kubernetes.

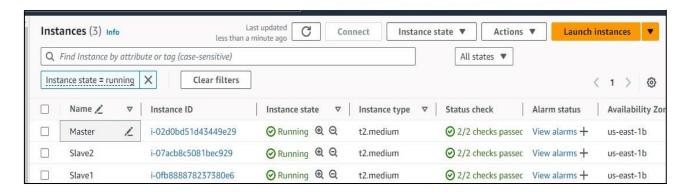

# Steps:

1. Create 3 EC2 Ubuntu Instances on AWS.

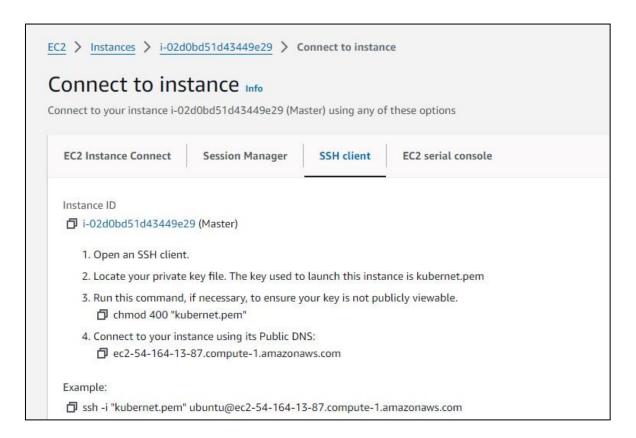

(Name 1 as Master, the other 2 as Slave1 and Slave2)

1. Created a master and 2 slaves:

- 2. Now click on connect to instance, then click on SSH client.
- 3. Now copy the ssh from the example and paste it on command prompt.(I used gitbash)

#### Commands:

- 4. Now since you are on GitBash, first type sudo su to perform the command as a root user
- 5. After this type on all 3 machines Yum install docker -y

```
Dependencies resolved.
                                           Architecture
                                                                      Version
                                                                                                                Repository
                                                                                                                                                 Size

```

6. To start the docker on master and slave perform this command: Systematl start docker

#### **Extra**

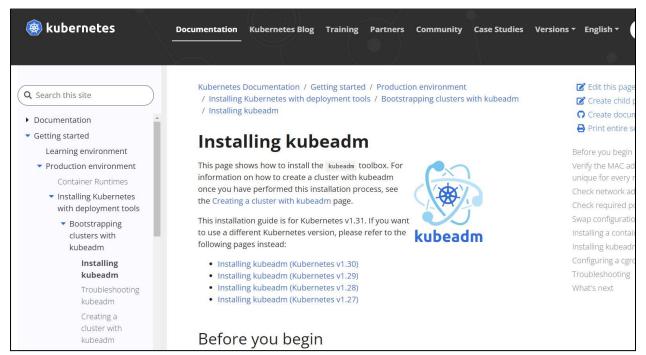

7. To check if docker is Installed successfully:

#### Docker -v or Docker -version

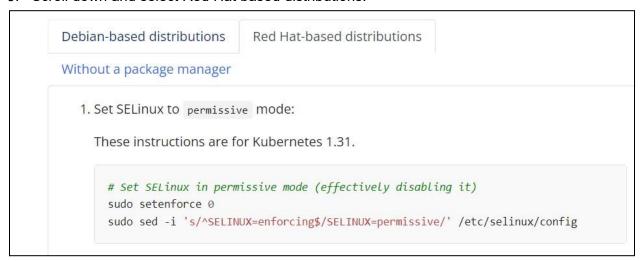

#### 8. Now to install kubeadm on master and slaves:

# Installing kubeadm:

Go the official documentation off kubeadm.

9. Scroll down and select Red Hat based distributions:

10. Now copy the command on all 3 machines:

Set SELinux to permissive mode:

These instructions are for Kubernetes 1.31.

# Set SELinux in permissive mode (effectively disabling it) sudo setenforce 0 sudo sed -i 's/^SELINUX=enforcing\$/SELINUX=permissive/' /etc/selinux/config

11. Now copy all the commands on the GitBash on all the 3 machines:

# This overwrites any existing configuration in /etc/yum.repos.d/kubernetes.repo cat <<EOF | sudo tee /etc/yum.repos.d/kubernetes.repo

[kubernetes] name=Kubernetes

baseurl=https://pkgs.k8s.io/core:/stable:/v1.31/rpm/ enabled=1 gpgcheck=1 gpgkey=https://pkgs.k8s.io/core:/stable:/v1.31/rpm/repodata/repomd.xml.key exclude=kubelet kubeadm kubectl cri-tools kubernetes-cni EOF

#Install kubelet, kubeadm and kubectl: sudo yum install -y kubelet kubeadm

kubectl --disableexcludes=kubernetes #(Optional) Enable the kubelet service

before running kubeadm:

sudo systemctl enable --now kubelet

```

[certs] Generating "front-proxy-client" certificate and key
[certs] Generating "etcd/ca" certificate and key
```

- 14. After this we will get 3 things:
  - The directory
  - Some export Statement
  - The most important thing the token to connect the slaves with the master.

# 15. Copy them one by one and paste it on the slaves:

```
To start using your cluster, you need to run the following as a regular user:

mkdir -p $HOME/.kube
sudo cp -i /etc/kubernetes/admin.conf $HOME/.kube/config
sudo chown $(id -u):$(id -g) $HOME/.kube/config

Alternatively, if you are the root user, you can run:

export KUBECONFIG=/etc/kubernetes/admin.conf

You should now deploy a pod network to the cluster.
Run "kubectl apply -f [podnetwork].yaml" with one of the options listed at:
 https://kubernetes.io/docs/concepts/cluster-administration/addons/

Then you can join any number of worker nodes by running the following on each as root:

kubeadm join 172.31.26.66:6443 --token grw4r4.gb3kkhb7392dnvjp \
 --discovery-token-ca-cert-hash sha256:b61f1de7eedb2c0dc0cc237d4629e9631920b63dd6634c3e22e76aaa36d01920
```

# 16. After pasting type kubectl get nodes:

### The nodes are connected successfully:
